

Method for remote control, system using the same method, and computer
program product performing the same method

FIELD OF THE INVENTION

5 The present invention relates to a remote control data processing
method in a remote control system including a client computer, a host computer,
and a network for linking them, a system using the method thereof, and a
computer program product performing the method thereof.

BACKGROUND OF THE INVENTION

10 ~~As Recently, as the communication networks have recently network is~~
expanded and computer systems mounting easy-to-use graphical user interface
are developed, remote control systems for controlling electronic appliances at
distant places through the network are being widely distributed~~distributing~~.

15 One of the problems of remote control by network is that it takes a
certain time to transmit a remote control signal over ~~for~~ a long distance. As a
result, a time delay occurs between the local operation and operation at the
distant place.

20 The delay time in the network becomes a serious problem in the case of
composite operations which are composed of plural operations. In such
composite operations, the interval between ~~of~~ one operation and another ~~other~~
is an important factor for judging what operation has been done. For example,
suppose ~~to open~~ a computer program is opened by double-clicking an icon on the
screen of a computer in a distant place.

25 An example of a problem in remote control which is caused by a delay
time in the network is explained below.

Fig. 8 is a configuration of a remote control system.

In Fig. 8, the remote control system contains a client computer 2, a host computer 1 which is controlled by the client computer 2 from a distant place, and a network 3 linking these computers.

The host computer 1 comprises an information processing unit 11, a display unit 12, a communication unit 13, and a pointing device 14. The display unit 12 displays the image information that is processed in the information processing unit 11. The communication unit 13 exchanges information with the network 3. The pointing device 14 manipulates the host computer 1.

The client computer 2 comprises an information processing unit 21, a display unit 22, a communication unit 23, and a pointing device ~~9~~24. The display unit 22 displays the image information that is processed in the information processing unit 21. The communication unit 23 exchanges information with the network 3. The pointing device ~~9~~24 manipulates the client computer 2.

The pointing devices 14, ~~9~~24 are a mouse, a digitizer, and other input devices.

The pointing devices 14, ~~9~~24 have on/off buttons for moving the pointer so as to indicate ~~for indicating~~ a position on the screen of the respective display units 12, 22, and to select ~~selecting~~ the object that is indicated by the pointer by inputting coordinates data.

The user can click the on/off button twice quickly without moving the pointing device (without updating the device coordinates data), which is called a double click. In this case, if the interval between the first click and second click is long, this operation is not recognized as a double click.

The network 3 is a wired or wireless network such as a local area network (LAN) or a wide area network (WAN).

The operation of the remote control system will now be ~~is~~ explained.

The host computer (hereinafter called host PC) 1 transmits the image information that is output in the display unit 12 to the communication unit 23 of the client computer (hereinafter called client PC) 2 from the communication unit 13 through the network 3. At this time, the client computer 2 processes the image information that is sent from the host computer 1 in the information processing unit 21, and outputs the processed image information to the display unit 22.

When the pointing device 9 ~~24~~ is manipulated in the client PC 2, this operation information is sent to the communication unit 13 from the communication unit 23 through the network 3. The host PC 1 processes the operation information that is sent from the client PC 2 as the operation information by manipulation of the pointing device 14.

The host PC 1, when the image information that is output in the display unit 12 is changed by manipulation of the pointing device 14, sends the differential image information before and after the change from the ~~first~~ communication unit 13 to the communication unit 23 of the client PC 2.

The client PC 2 updates the image information in the display unit 22 according to the differential image information that is sent from the host PC 1.

In this manner, the host PC 1 which is located in a distant place can be operated from the client PC 2, and the same image information as in the display unit 12 of the host PC 1 can be shown in the display unit 22 of the client PC 2.

In this remote control system, if the delay time in the network is large, the following phenomena may occur.

i) If the double click which is entered in the client PC 2 is transmitted to the host PC 1 as operation information, it is not processed as a double click in

the host PC 1.

ii) Two single clicks which are entered in the client PC 2 are processed as a double click at the host PC 1.

Such incorrect processes may occur if the time interval between packets is changed by an irregular delay characteristic of the network while the data of two packets showing two successive presses on the button of the pointing device 9 24 flow on the network. At this time, the host PC 1 recognizes and processes as if the button was pressed at a different timing from the operation in transmission.

Moreover, as compared with the case of the user manipulating the host PC 1 directly, when in case that the host PC 1 is remote-controlled by the client PC 2, it takes time until the input result at the client PC 2 is reflected in the first display unit 12 of the host side. Therefore, the user of the client computer 2 takes time until knowing that the double click is correctly entered at the host PC 1. As a result, ~~the working efficiency decreases~~ drops.

SUMMARY OF THE INVENTION

It is therefore ~~hence~~ an object of the invention to present a method, system and a computer program product for processing remote control data even if the delay time in the network is large. In the present invention, the host computer terminal and client computer terminal are coupled through the network, and the remote control system is built up.

The client computer terminal comprises:-

——an information processing unit,—

——a communication unit for exchanging information with the network,
and—

——a pointing device for controlling the client computer terminal.

In this client computer terminal, the information processing unit transforms the operating procedure of the pointing device into the operation information including the button state data, coordinates data, and time interval data between the operations, and the communication unit sends the
5 information to the network.

On the other hand, the host computer terminal comprises an information processing unit and a communication unit which are coupled with the network. In the host computer terminal, the information processing unit decomposes the operation information that is received in its communication
10 unit into the operating procedure at the client terminal, and reproduces the operating procedure.

In this manner, the operating procedure of the pointing device at the client terminal can be reproduced at the host terminal without having the effects of an irregular delay of the network.

15

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 shows a configuration of a remote control system in an embodiment of the present invention.

Fig. 2A is a functional block diagram of an information processing unit of a client PC in the embodiment of the present invention.

10 the present invention.

Fig. 8 shows a configuration of a conventional remote control system.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT OF THE INVENTION

15 An embodiment of the present invention is explained with reference by ~~referring to Figs. Fig-1 to Fig-7.~~

A configuration of the remote control system in the embodiment is explained with reference ~~by referring to Fig. 1 and Fig. 2.~~

Fig. 3 to Fig. 6 are flowcharts showing the transmission process of an
20 operation packet about a pointing device 44 of the client computer in the embodiment.

In Fig. 1, information processing units 31, 41 monitor the operation of pointing devices 34, 44 of a host computer (host PC) 30 and a client computer (client PC) 40, respectively.

25 As the pointing device is manipulated, when the indicated coordinates are moved or the on/off of the button is changed, the processing units 31, 41 generate data, and display the coordinates data and the button status data on

the screen of the display units 32, 42 ~~unit~~ as a pointer, respectively. The processing units 31, 41 form data into packets, and send the data to the counterpart information processing unit 31, 41 of the partner of communication through communication units 33, 43 and a network 70.

5 When the button of the pointing device is turned on, off and on within a maximum click interval T1 without a change in the coordinates that are indicated by the pointing device, the processing units 31, 41 judge an input of double click.

 The processing units 31, 41 have a timer for measuring the maximum
10 click interval T1.

 The timer has a function like a watchdog timer, and measures the time from a first click to a second click on the pointing device. The timer setting time T1 is counted from 0 ~~seconds~~~~second~~, and is the duration from the start of an operation at an arbitrary timing until the end of the operation.

15 Fig. 2A is a functional block diagram showing the operation of the information processing unit 41 of the client PC 40.

 Fig. 2B is a functional block diagram showing the operation of the information processing unit 31 of the host PC 30.

 In Fig. 2A, a timer 60 counts the time as the reference for detecting the
20 operation of the pointing device 44. An operation determining unit 62 detects and judges the move of the pointing device 44 and an on/off operation of the ~~its~~ button of the pointing device 44. Based on a ~~On the basis of~~ result of this detection and judgement, the operation determining unit 62 further generates operation information. This operation information includes the coordinates
25 data showing the move of the pointing device 44, button status data showing the on/off operation of the button, and the time between the operations. An informing unit 64 outputs data for informing the user of the operation of the

pointing device 44. A transmission data output unit 66 outputs the data regarding about the operation of the pointing device, including the operation information, to the network 70 through the communication unit 43.

In Fig. 2B, a timer 50 counts the time for judging a double click of the pointing device 34 at the host PC 30. A watching unit 52 monitors the reception of data regarding about the operation of the pointing device 44 including the operation information that is sent from the client PC 40. A data determining unit 54 judges the operation of the pointing device 44 at the client PC 40 based on the data including the operation information that is sent from the client PC 40. A reproducing unit 56 reproduces the operation of the pointing device 44 at the client PC 40 depending on the data that is judged by the data determining unit 54 at the host PC 30.

The operation in the client PC 40 will now be ~~is~~ explained with reference by referring to Figs. 3-6 ~~Fig. 3 to Fig. 6~~.

The remote control data processing in the client PC 40 includes the following processing in the input of a double click.

- 1) Judging the first button to be ON,
- 2) Judging the first button to be OFF after judging the first button to be ON,
- 3) Judging the second button to be ON after judging the first button to be OFF, and
- 4) Processing before advancing to the first button ON judging process in a double click input, after the double click input or after going out of the double click input condition.

The procedure will now be ~~is~~ explained sequentially from the flowchart in Fig. 3.

Fig. 3 is a flowchart showing the first button ON judging process in a

double click input in the client PC 40.

In Fig. 3, at the click interval acquiring step S101, the timer 60 acquires the maximum click interval T1 for judging a double click from the host PC 30.

At the first watching step S102, the operation determining unit 62
5 judges whether or not ~~if~~ the client side pointing device 44 has been operated ~~or not~~. If the pointing device 44 has not been operated, the watching step continues until the operation is recognized. When the pointing device 44 is operated, the process goes to the first move judging step S103.

At step S103, the operation determining unit 62 judges whether or not
10 ~~if~~ the operation of the pointing device 44 is accompanied by a move ~~or not~~. If the pointing device 44 has not been moved, it is judged ~~regarded~~ that the button of the pointing device 44 is turned on, and the process goes to the first timer start step S104. If the pointing device 44 has been moved, the process goes to the first operation packet transmit step S105.

15 At step S104, the timer 60 starts, and the flowchart shown in Fig. 4 is started.

At step S105, the transmission data output unit 66 sends a coordinates data packet showing the move operation that is generated in the operation determining unit 62 to the host PC 30. After transmission of the coordinates
20 data packet, the process goes to the first ON judging step S106.

At step S106, the determining unit 62 judges whether or not ~~if~~ the button of the pointing device 44 has been turned on ~~or not~~.

If the button is turned on, the flowchart shown in Fig. 6 is started.

If the button is not turned on, going back to step S102, the same process
25 is repeated.

The flowchart shown in Fig. 4 will now be ~~is~~ explained.

Fig. 4 is a flowchart showing the first button OFF judging process after

the first button is judged to be ON in a double click input in the client computer
40.

At the first lapse time measuring step S201, the timer 60 measures the
lapse time, and judges if the time has exceeded T1 or not. When the lapse time
5 exceeds exceeding-T1, the process goes to the first timer stop step S204.
Otherwise, the process goes to the second watching step S202.

At step 202, the determining unit 62 judges whether or not if the
pointing device 44 is operated or not. If the pointing device 44 is judged not to
be operated, going back to step S201, the timer continues to watch until the
10 lapse time exceeds exceeding-time T1.

When the pointing device is judged to be operated, the process goes to
the second move judging step S203.

At step S203, it is judged if the operation of the pointing device 44 is
accompanied by a move or not.

15 If the pointing device 44 is not accompanied by a moved, the
determining unit 62 judges that the device 44 is turned off, and the flowchart in
Fig. 5 is started.

On the other hand, if the pointing device 44 is judged to have been
accompanied by a If-moved, it is regarded that the pointing device 44 is moved
20 with the button remaining in the ON position, and the process goes to the
second timer stop step S206.

At step S206, the timer 60 stops, and the transmission data output unit
66 transmits the packet data showing the button ON to the host PC 30 through
the communication unit 43 (the second ON packet transmit step S207).

25 In succession, the coordinates data packet of the pointing device 44 is
sent to the host PC 30 (the second operation packet send step S208).

After transmission of the coordinates data packet of the pointing device

44, the process goes to the first OFF judging step S209.

At step S209, the determining unit 62 judges whether or not ~~if~~ the ON state button is manipulated to the OFF state ~~or not~~.

5 If the button is manipulated to the OFF state, going back to step S102 in Fig. 1, the same process is repeated.

When the button remains in the ON position, the flowchart in Fig. 6 is started.

At the first timer stop step S204, the timer 60 stops, and the process goes to first ON packet send step S205.

10 At step S205, the output unit 66 transmits the button ON packet data to the host PC 30, and the flowchart in Fig. 6 is started.

The steps shown in the flowchart in Fig. 5 will now be ~~are~~ explained.

Fig. 5 is a flowchart showing the second button ON judging process after judging the first button to be OFF in a double click input in the client PC
15 40.

At the second lapse time measuring step S301, the timer 60 measures the lapse time, and judges whether or not ~~if~~ the time has exceeded T1 ~~or not~~. When the lapse time exceeds ~~exceeding~~ T1, the process goes to the fourth timer stop step S307. Otherwise, the process goes to the third watching step S302.

20 At step 302, the determining unit 62 judges whether or not ~~if~~ the second pointing device 44 is operated ~~or not~~. If the pointing device 44 is not operated, going back to step S301, the timer continues to watch until the lapse time exceeds ~~exceeding~~ time T1. When operated, the process goes to the third timer stop step S303.

25 At step S303, the timer 60 stops, and the process goes to the third move judging step S304.

At step S304, the determining unit 62 judges whether or not ~~if~~ the

operation of the pointing device 44 of the client PC 40 is accompanied by a move
~~or not.~~

If the pointing device 44 has not been accompanied by a move~~moved~~,
the determining unit 62 judges that the device 44 is turned off. At this time,
5 the output unit 66 transmits an operation command showing a double click to
the host PC 30 (double click send step S305).

Consequently, the informing unit 64 transmits data to an audio output
unit or a video output unit of the client PC 40 so as to inform the user of the
transmission of a double click command by voice or display (informing step
10 S306).

The next process goes to step S401 in Fig. 6.

If the pointing device 44 is moved by an operation, on the other hand,
the determining unit 62 judges that the button is turned on (step S102), and
then turned off (step S202), and consequently that the pointing device 44 is
15 moved. Therefore, ~~first,~~ the transmission data output unit 66 first transmits
packet data showing the button to be ON to the host PC 30 (fourth ON packet
send step S310).

Next, the transmission data output unit 66 transmits packet data
showing the button to be OFF to the host computer 30 (fourth OFF packet send
20 step S311).

Further, the transmission data output unit 66 transmits the coordinates
data showing the coordinates of the moved position of the pointing device 44 to
the host computer 30 (third operation packet send step S312). Then, the
process goes to the third ON judging step S313.

25 At the second lapse time measuring step S301, when the lapse time of
the timer 60 exceeds T1, the process goes to the fourth timer stop step S307.

At step S307, the timer 60 stops, and the process goes to the third ON

packet transmit step S308.

At step S308, the transmission data output unit 66 transmits the packet data showing a ~~an~~-button to be ON to the host PC 30, and the process goes to third OFF packet send step S309.

5 At step S309, the transmission data output unit 66 transmits the packet data showing a ~~an~~-button to be OFF to the host PC 30, and the process returns to step S102 in Fig. 1.

At the third ON judging step S313, the operation determining unit 62 judges whether or not if the operation judged at step S302 is an ON operation of
10 the button-or-not.

In the case of an ON operation of the button, the process goes to the fourth watching step S401 in Fig. 6.

Otherwise, the process returns to step S102 in Fig. 1.

The flowchart shown in Fig. 6 will now be is-explained.

15 Fig. 6 is a flowchart showing the process until advancing to the first button ON judging process in a double click input after the double click input or after going out of the double click input condition in the client PC 40.

At the fourth watching step S401, the determining unit 62 judges whether or not if the second pointing device 44 is operated-~~or-not~~. If the
20 pointing device 44 is not operated, watching continues until an operation of the pointing device 44 is recognized.

When the pointing device 44 is operated, the process goes to the fourth operation packet send step S402.

At step S402, the transmission data output unit 66 transmits the
25 operation packet showing the operation judged at step S401 to the host computer 1, and the process goes to the fourth OFF judging step S403.

At step S403, the determining unit 62 judges whether or not if the

operation that is judged at step S401 is an OFF operation of the button ~~or not~~.

In the case of the OFF operation of the button, the process returns to step S102 in Fig. 1.

Otherwise, the process returns to step S401.

5 Thus, in the information processing unit 41 of the client PC 40, the operation determining unit 62 judges the operation of the pointing device 44, and generates operation information as packet data. The data output unit 66 outputs the operation information as packet data to the network 70 through the communication unit 43.

10 The processing ~~Process~~ of remote control data in the host PC 30 will now be ~~is explained below~~.

Fig. 7 is a flowchart showing the reception process of an operation packet, that is, operation information regarding ~~about~~ the pointing device 44 of the client PC 40 in the host PC 30 in the embodiment.

15 Herein, T2 is the maximum click interval for judging a double click by the ~~button~~ ON-OFF-ON button operation of the pointing device 34 in the host PC 30. The timer 50 stops automatically when exceeding the time T2.

20 In Fig. 7, at a reception watching step S501, the watching unit 52 judges whether or not ~~if~~ the operation packet data that is transmitted from the client computer 40 is received ~~or not~~.

If the operation packet data is not received, the watching unit 52 continues to monitor until the reception of the operation packet data is confirmed.

25 When the operation packet data is received, the process goes to the fourth move judging step S502.

At step S502, the data determining unit 54 judges whether or not ~~if~~ the operation packet data that is received at step S501 shows the operation as

being accompanied by a move of the pointing device 44 of the coordinates ~~or not~~.

If accompanied by a move of the coordinates, the process goes to the fourth timer stop step S503. At this step, the timer 50 stops, and the process goes to the double click judging step S504.

5 | If not accompanied by a move, the process goes to step S504.

At step S504, the data determining unit 54 judges whether or not if the operation packet data that is received at step S501 shows a double click ~~or not~~.

If the received operation packet data shows a double click, the process goes to the first timer operation watching step S505.

10 | If the received operation packet data does not show a double click, the process goes to the button operation judging step S509.

At the first timer operation watching step S505, the watching unit 52 judges whether or not if the timer 50 is in operation ~~or not~~. If the timer 50 is in operation, the watching unit 52 waits until stopping automatically. Then,
15 | the reproducing unit 56, after the first ON reproducing step S506, the OFF reproducing step S507, and the second ON reproducing step S508, reproduces the ON-OFF-ON operation of the button of the pointing device 44 ~~14~~ so as to be recognized as a double click in the host PC 30.

If judged not to be a double click at step S504, the process goes to the
20 | button operation judging step S509.

At step S501, the data determining unit 54 checks whether or not if the received operation packet shows the operation of changing the button of the pointing device 44 from ON to OFF ~~or not~~. If Yes, the process goes to the second timer operation watching step S510. Otherwise, the process goes to the
25 | operation packet reproducing step S512 for reproducing the button operation.

At the second timer watching step S510, the data determining unit 54 judges whether or not if the timer 50 is in operation ~~or not~~. During operation,

waiting until stopping automatically, the process goes to the second timer start step S511.

At step S511, the timer 50 starts, and the process goes to the operation packet reproducing step S512.

5 | At step S512, the reproducing unit 56 reproduces the operation that is indicated by the operation packet received at step S501.

Thus, in the information processing unit 31, the data determining unit
54 in the host PC 30 judges the operation of the pointing device 44 in the client
PC 40 by the data including the operation information that is sent from the
10 client PC 40. The reproducing unit 56 reproduces the operation of the pointing
device 44 in the client PC at the host PC 30 depending on the data that is
judged by the data determining unit 54.

According to the embodiment of the present invention, the double click
is transmitted from the client computer to the host computer, not as ~~the plural~~
15 operation packets showing an on/off operation of the button of the pointing
device of the client computer, but instead as one operation packet showing the
double click. Therefore, even if the delay time of the network is large, the host
computer correctly recognizes the input of a double click at the client computer.

Moreover, the user of the client computer, by voice or display, is notified
20 of the transmission of an operation packet showing a double click input from
the client computer to the host computer ~~is noticed to the user of the client~~
~~computer by voice or display~~. Thus, the user instantly understands the input
of a double click.

As described herein, in the remote control data processing method and
25 system of the present invention, the information processing unit of the client
computer converts the operating procedure of the pointing device of the client
computer into operation information including button status data, coordinates

data, and interval data between operations, and transmits the operation information to the host computer. In the information processing unit of at the host computer, the operating procedure of the client computer is reproduced from the received operation information. Thus, even if the delay time of the
5 | network is large, the host computer correctly recognizes the operation that is entered in the client computer.

In the foregoing embodiment, the specific method and device are explained. The present invention may also be ~~also~~ realized by using a computer program product containing a computer program for executing the
10 | method shown in the embodiment by a computer.

ABSTRACT

A system which provides for the remote control of a host computer by a client computer ~~is disclosed~~. The client computer converts the operating procedure of its pointing device into operation information including data
5 regarding a ~~about~~ switch operation, coordinates data, and time interval data between operations, and transmits the operation information to the host computer. The host computer decomposes the received operation information into the original operating procedure, and reproduces the original operating
10 procedure. Thus, the operating procedure of the pointing device that is transmitted to the host computer from the client computer is prevented from having the effects of an irregular delay of the network.
